Brief Introduction

In this talk we revisit some of the MOST BASIC IDEAS IN IMAGE PROCESSING

I will try to convince you that even there, core concepts that seem fixed and settled MIGHT BE QUESTIONED AND APPROACHED IN A NEW WAY

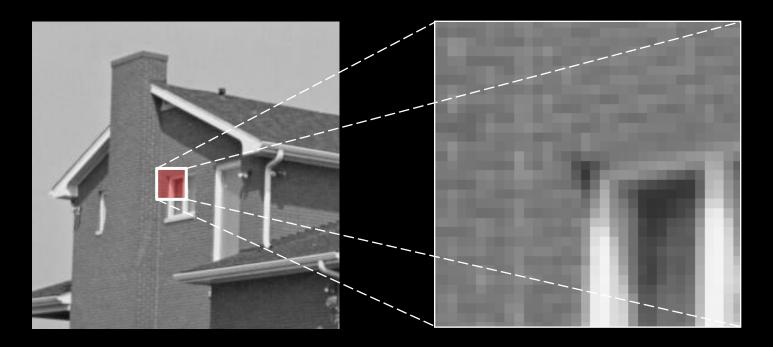

Part I

$2D \rightarrow 1D$ Conversion

Here is an Image ...

An image is a 2D signal. As such, there is no sense of causality between the pixels.

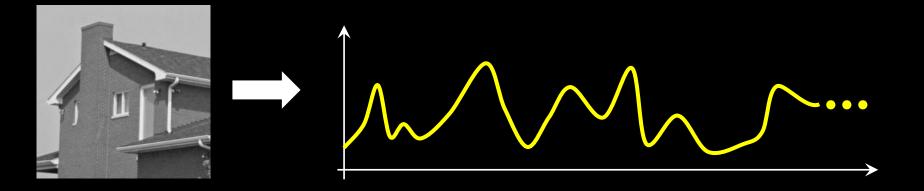

In this talk, we focus on the need to process such images, performing tasks such as :

- Noise removal.
- □ Filling-in missing values.
- Restoration (deblurring, super-resolution).
- Reconstruction (e.g. Tomography).
- Dithering.
- Compression.

$2D \rightarrow 1D$ Conversion ?

Often times, a proposed solution to any of the above tasks starts by 2D to 1D conversion :

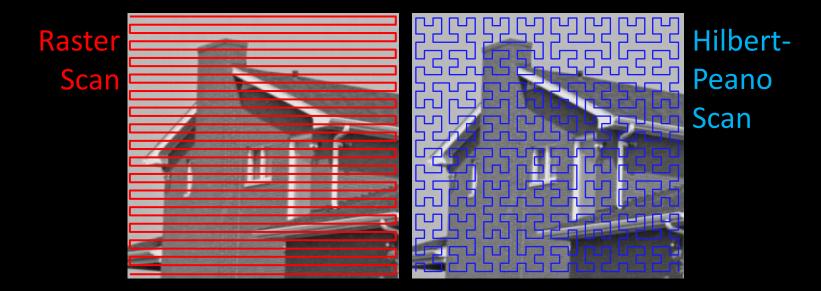

After such a conversion, the image is treated as a regular 1D signal, with implied sampled order and causality.

$2D \rightarrow 1D$: How to Convert ?

There are many ways to convert an image into a 1D signal. Two very common methods are:

□ Note that both are "space-filling curves" and image-independent, but we need not restrict ourselves to these types of 2D →1D conversions.

The scientific literature on image processing is loaded with such conversions, and the reasons are many:

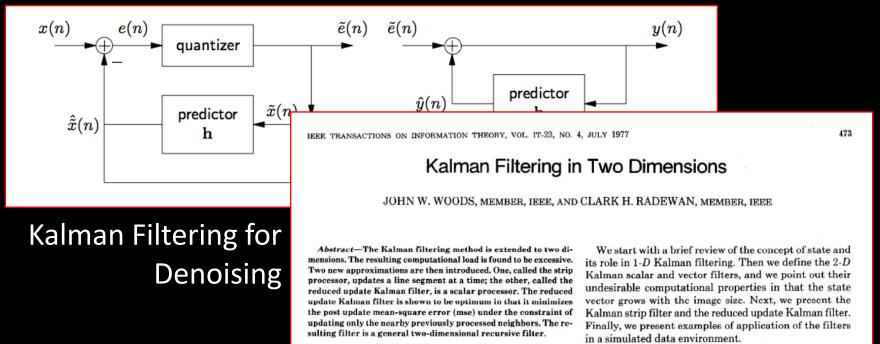

- Because serializing the signal helps later treatment.
- Because (imposed) causality can simplify things.
- Because this enables us to borrow ideas from 1D signal processing (e.g. Kalman filter, recursive filters, adaptive filters, prediction, ...).
- Because of memory considerations.
- Because of run-time considerations.

Note that it is never claimed that $2D \rightarrow 1D$ would lead to improved performance in terms of output quality

$2D \rightarrow 1D$ Processing Examples

DPCM Image Compression

While this $2D \rightarrow 1D$ trend is an "old-fashion" trick, it is still very much active and popular in industry and academic work.

$2D \rightarrow 1D$: Is It a Good Idea ?

□ If anyone proposes a solution to an image processing problem that starts by a 2D → 1D conversion, we should immediately think:

SUBOPTIMAL SOLUTION !!

□ The reasons for this belief are obvious:

- Loss of neighborhood relations.
- Unnatural causality.

□ So, we conclude that this approach is not a good idea !!

ARE WE SURE ?

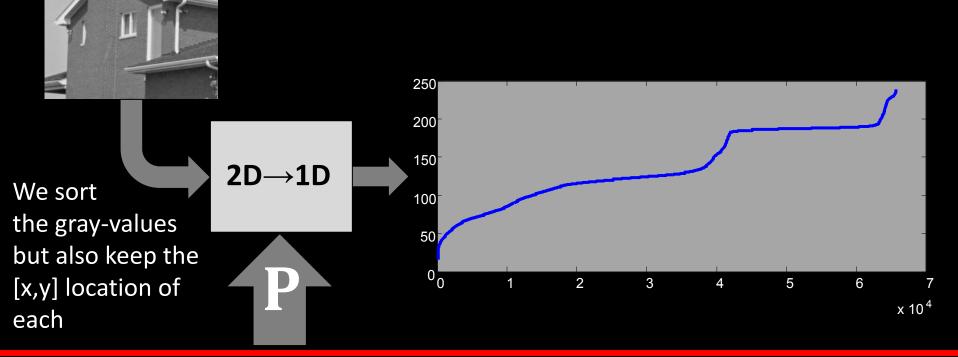

Part II Our Core Idea

Lets Propose a New 2D \rightarrow 1D Conversion

How about permuting the pixels into a 1D signal by a

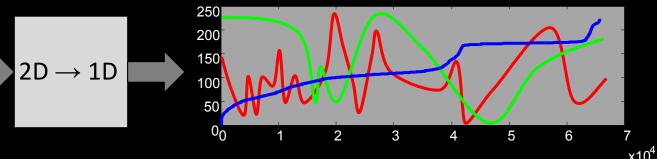

SORT OPERATION ?

New 2D \rightarrow 1D Conversion : Smoothness

Given any 2D \rightarrow 1D conversion based on a permutation **P**, we may ask how smooth is the resulting 1D signal obtained :

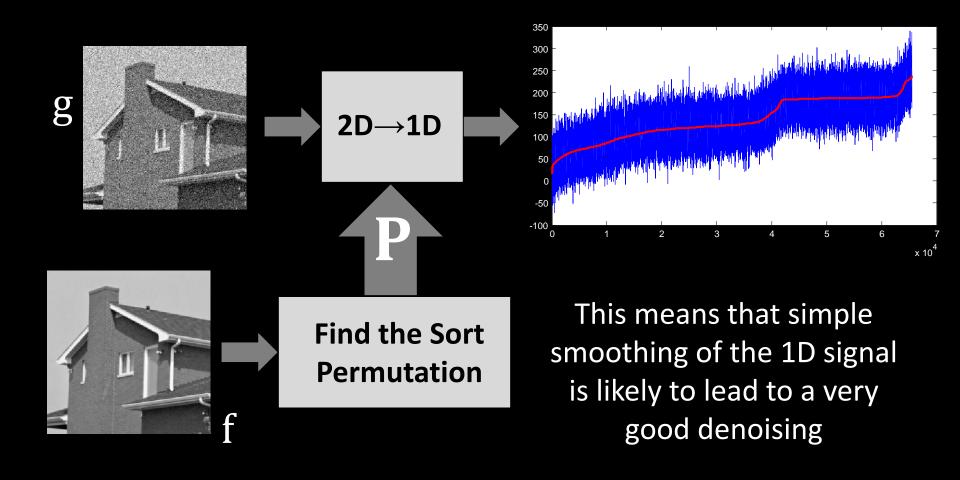

TV{f, **P**} =
$$\sum_{k=2}^{N} |f_P(k) - f_P(k-1)|$$

The sort-ordering leads to the smallest possible TV measure, i.e. it is the smoothest possible.

☐ Who cares? We all do, as we will see hereafter.

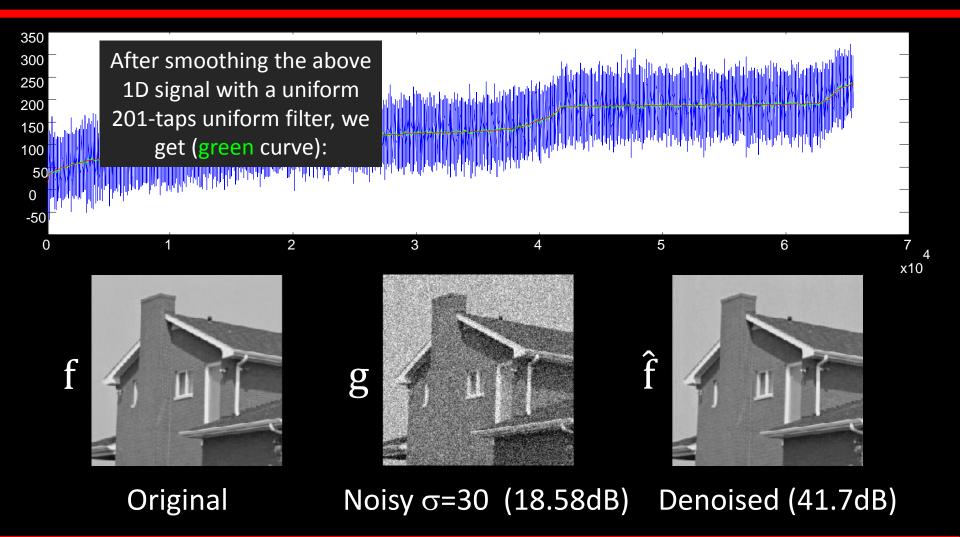

New 2D \rightarrow 1D Conversion : An Example

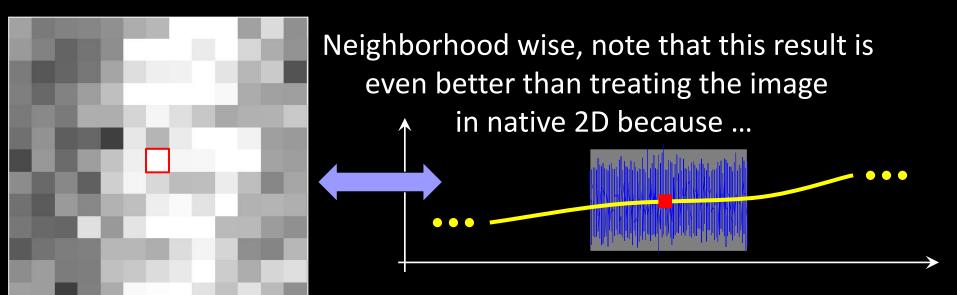

New 2D \rightarrow 1D Conversion : An Example

This denoising result we just got is nothing short of amazing, and it is far better than any known method

Is it real? Is it fair?

This is Just Great! Isn't It?

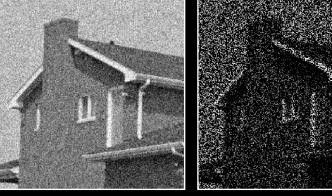

All this is wonderful ... but ...

Given a corrupted image (noisy, blurred, missing pixels, ...)

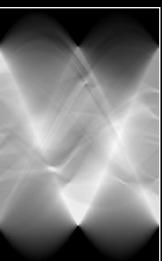

WE CANNOT KNOW THE SORTING PERMUTATION OPERATOR

So the above result is impractical.

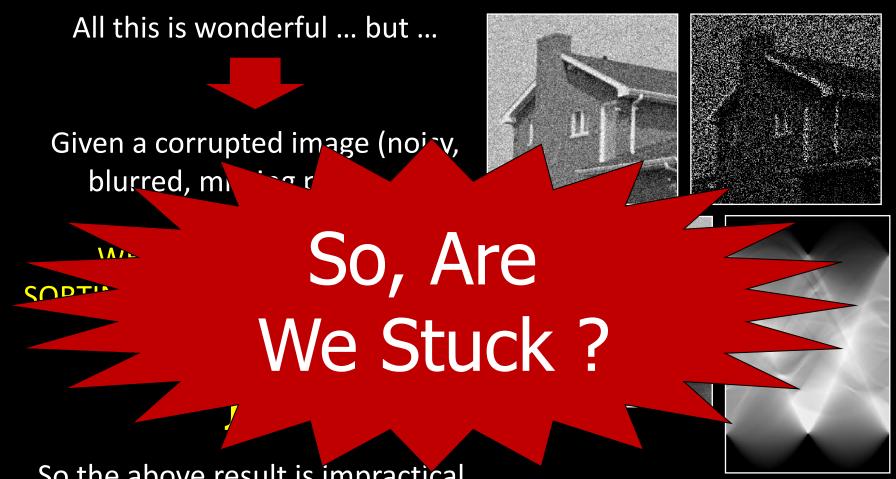

This is Just Great! Isn't It?

So the above result is impractical.

We Need an Alternative for Constructing P

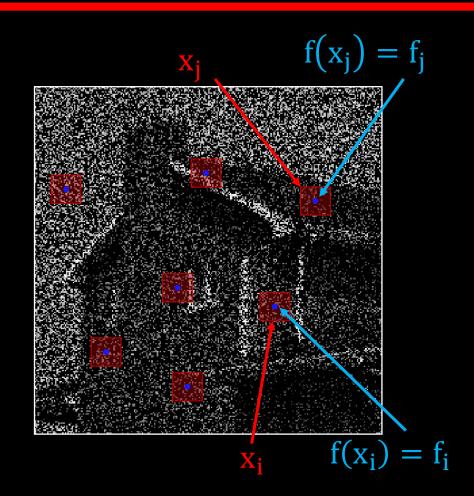

Our Goal – Sorting the pixels based on their TRUE gray value

The problem – the given data is corrupted and thus pixel gray-values are not to be trusted

The idea: Assign a feature vector **x** to each pixel, to enrich its description

Our approach: Every pixel will be "represented" by the patch around it

> We will design **P** based on these feature vectors

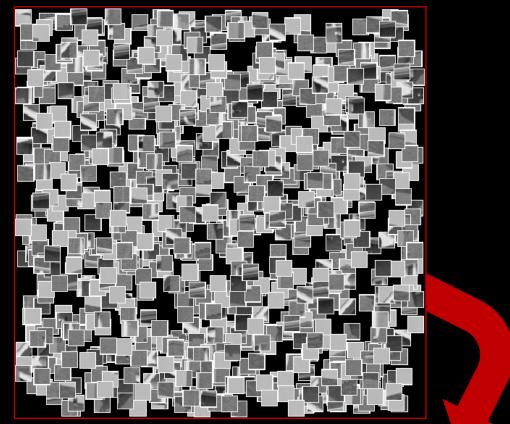

An Alternative for Constructing P

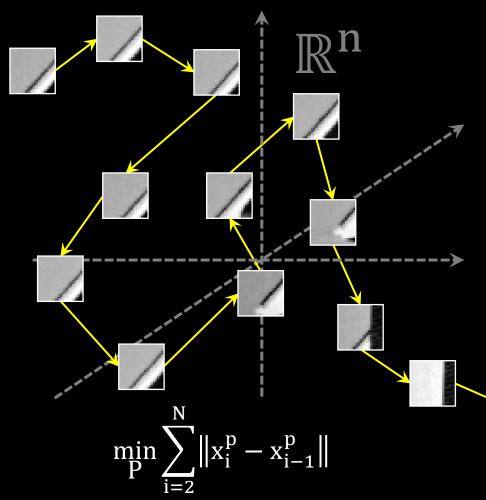

We will construct **P** by the following stages:

- Break the image into all its overlapping patches.
- 2. Each patch represents the pixel in its center.
- 3. Find the SHORTEST PATH passing through the feature vectors (TSP).
- 4. This ordering induces the pixel ordering **P**.

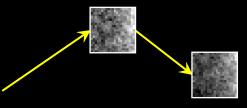

Traveling Salesman Problem (TSP)

□ Patches x_i of size √n × √n are points in ℝⁿ.
 □ In the Traveling Salesman Problem we seek the shortest path that visits every point.
 □ TSP in general is too hard to solve, and thus approximation algorithms are used.

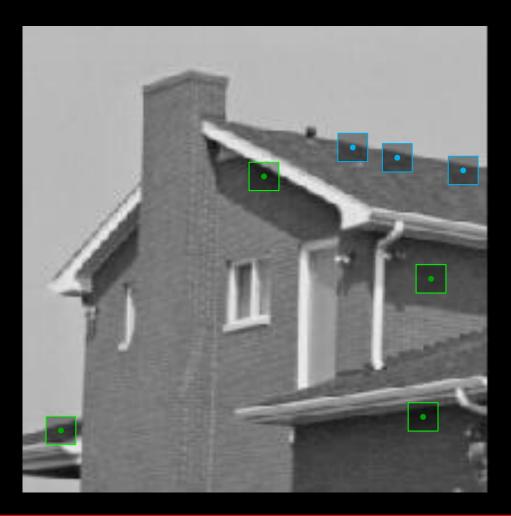

The Proposed Alternative : A Closer Look

Observation 1: Do we Get P?

If two pixels have the same (or close) gray value, this does not mean that their patches are alike. However ... If several patches are alike, their corresponding centers are likely to be close-by in gray-value

Thus, the proposed ordering will not reproduce the P, but at least get close to it, preserving some of the order.

The Proposed Alternative : A Closer Look

Observation 2: "Shortest-Path" ?

- In the shortest-path (and TSP), the path visits every point once, which aligns with our desire to permute the pixels and never replicate them.
- If the patch-size is reduced to 1×1 pixels, and the process is applied on the original (true) image, the obtained ordering is exactly P.

TSP Greedy Approximation:

- Initialize with an arbitrary index j;
- o Initialize the set of chosen indices to $\Omega(1)=\{j\};$
- o Repeat k=1:1:N-1 times:
 - Find x_i the nearest neighbor to $x_{\Omega(k)}$ such that $i \not\in \Omega$;
 - Set $\Omega(k+1) = \{i\};$

 \circ Result: the set Ω holds the proposed ordering.

$$\min_{\mathbf{P}} \sum_{k=2}^{N} |f_{P}(k) - f_{P}(k-1)| \qquad \min_{\mathbf{P}} \sum_{i=2}^{N} ||x_{i}^{p} - x_{i-1}^{p}||$$

The Proposed Alternative : A Closer Look

Observation 3: Corrupted Data ?

- If we stick to patches of size 1×1 pixels, we will simply sort the pixels in the degraded image – this is not good nor informative for anything.
- The chosen approach has a robustness w.r.t. the degradation, as we rely on patches instead of individual pixels.

$$\begin{aligned} & \operatorname{Argmin}_{P} \sum_{i=2}^{N} \left\| x_{i}^{p} - x_{i-1}^{p} \right\| \\ & \approx \operatorname{Argmin}_{P} \sum_{i=2}^{N} \left\| \widetilde{x}_{i}^{p} - \widetilde{x}_{i-1}^{p} \right\| \end{aligned}$$

The order is similar, not necessarily the distances themselves

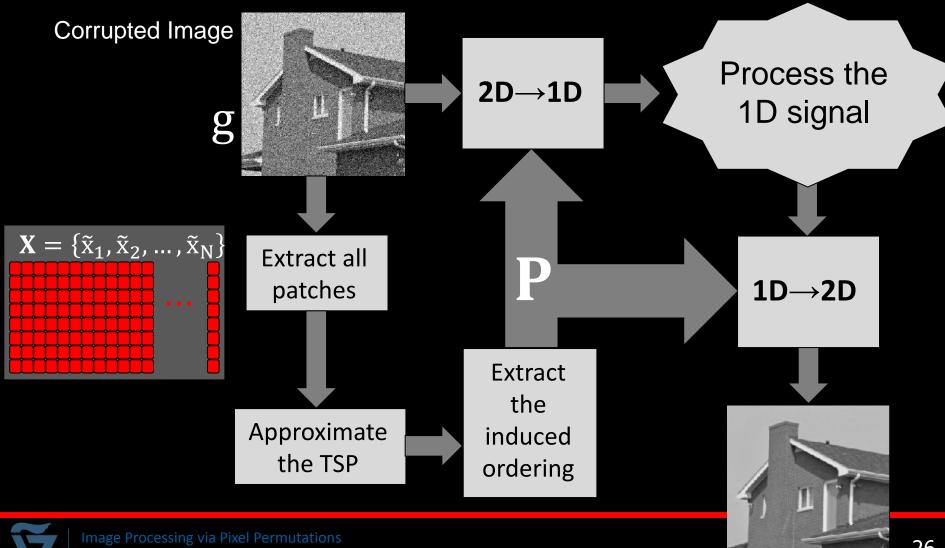

Part III

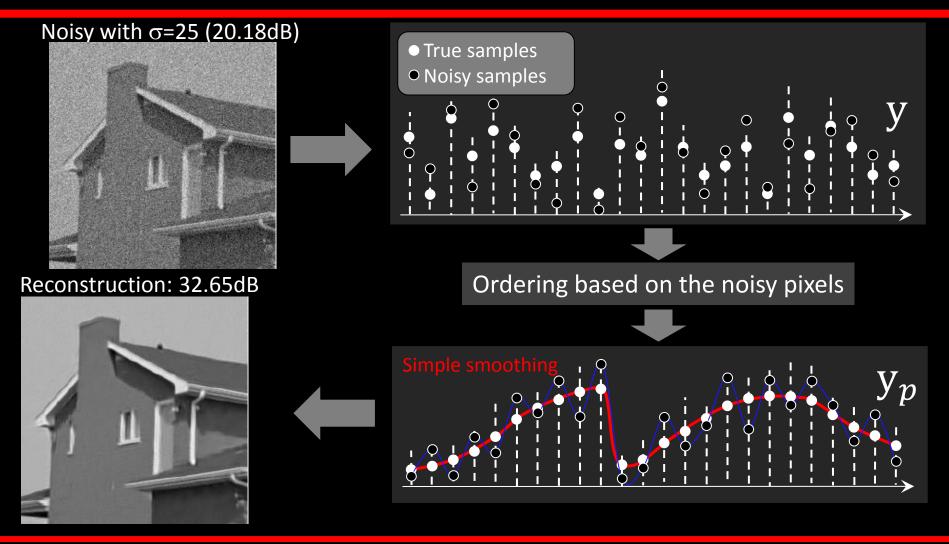

Image Denoising & Inpainting

The Core Scheme

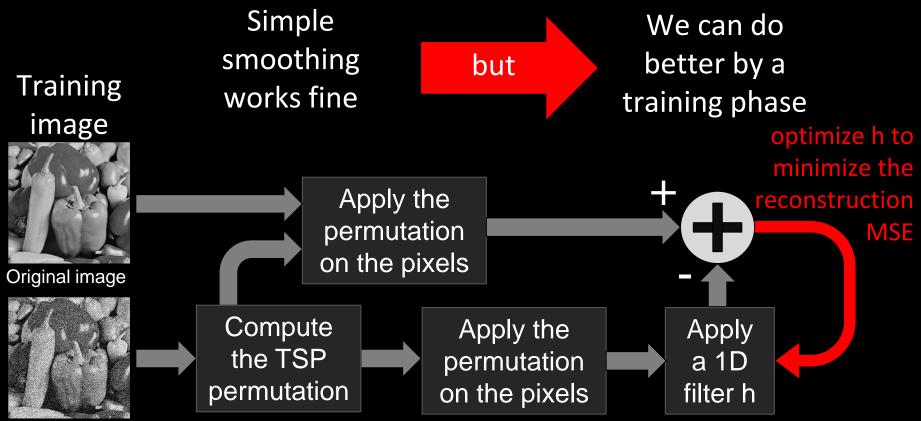

Intuition: Why Should This Work?

The "Simple Smoothing" We Do

Noisy image

Naturally, this is done off-line and on other images

Filtering – A Further Improvement

Cluster the patches to smooth and textured sets, and train a filter per each separately

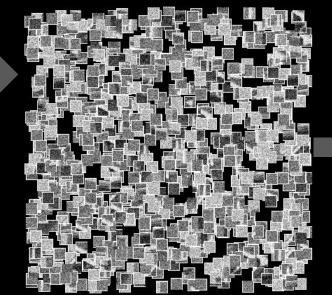

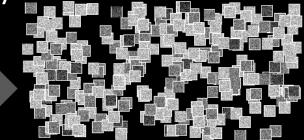

The results we show hereafter were obtained by:

- (i) Cycle-spinning
- (ii) Sub-image averaging
- (iii) Two iterations
- (iv) Learning the filter, and
- (v) Switched smoothing.

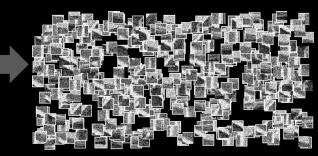

Based on patch-STD

Denoising Results Using Patch-Reordering

Image			σ/PSNR [dB]	
		10 / 28.14	25 / 20.18	50 / 14.16
Lena	K-SVD	35.49	31.36	27.82
	1 st iteration	35.33	31.58	28.54
	2 nd iteration	35.41	31.81	29.00
Barbara	K-SVD	34.41	29.53	25.40
	1 st iteration	34.48	30.46	27.17
	2 nd iteration	34.46	30.54	27.45
House	K-SVD	36.00	32.12	28.15
	1 st iteration	35.58	32.48	29.37
	2 nd iteration	35.94	32.65	29.93

Bottom line: (1) This idea works very well;

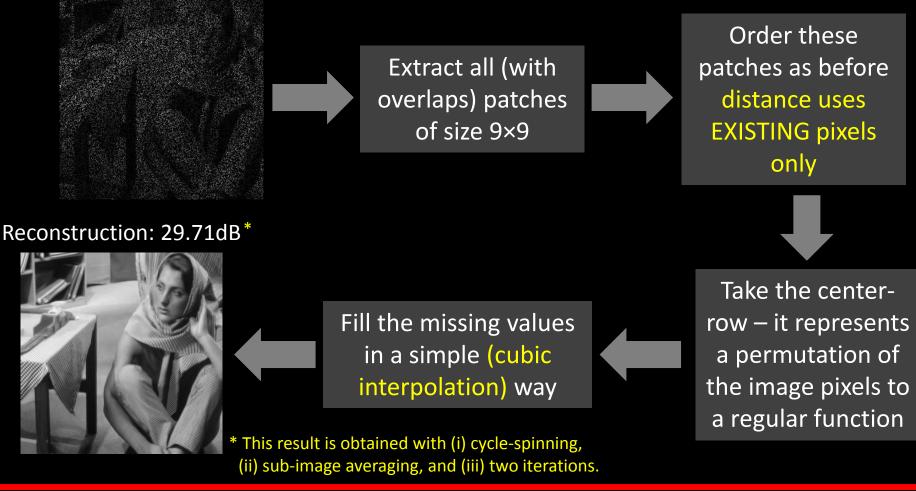

(2) It is especially competitive for high noise levels; and

(3) A second iteration almost always pays off.

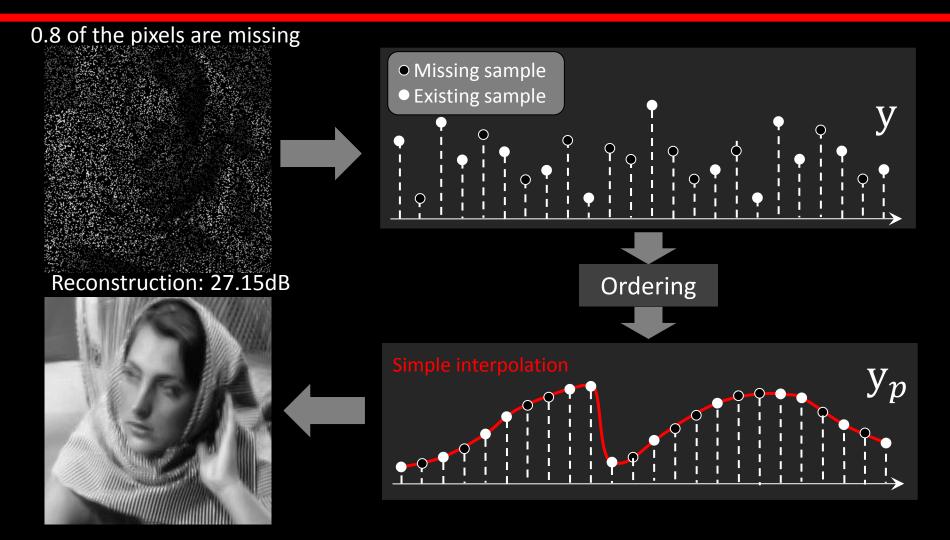

What About Inpainting?

0.8 of the pixels are missing

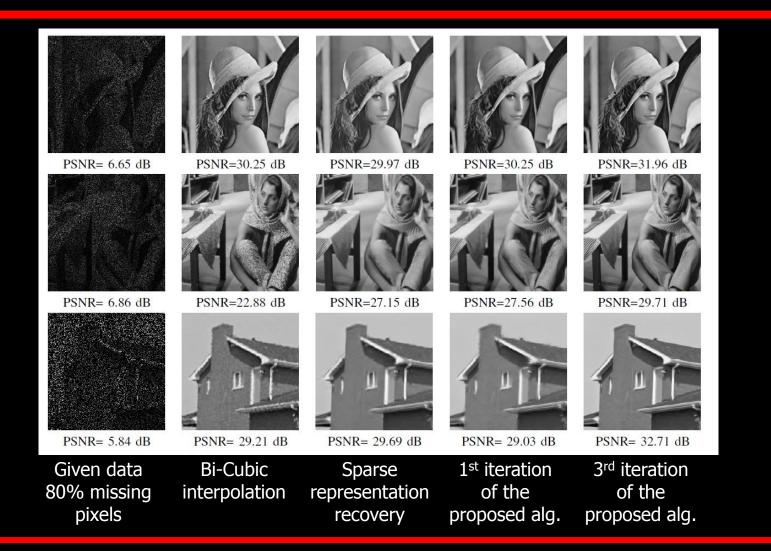

The Rationale

Inpainting Results – Examples

Inpainting Results

Ima

Len

Bark

Hou

Reconstruction results from 80% missing pixels using various methods:

ge	Method	PSNR [dB]
а	Bi-Cubic	30.25
	DCT + OMP	29.97
	Proposed (1 st iter.)	30.25
	Proposed (2 nd iter.)	31.80
	Proposed (3 rd iter.)	31.96
bara	Bi-Cubic	22.88
	DCT + OMP	27.15
	Proposed (1 st iter.)	27.56
	Proposed (2 nd iter.)	29.34
	Proposed (3 rd iter.)	29.71
ISE	Bi-Cubic	29.21
	DCT + OMP	29.69
	Proposed (1 st iter.)	29.03
	Proposed (2 nd iter.)	32.10
	Proposed (3 rd iter.)	32.71

Bottom line:

- This idea works very well;
- (2) It is operating much better than the classic sparse-rep. approach; and
- (3) Using more iterations always pays off, and substantially so.

Part IV

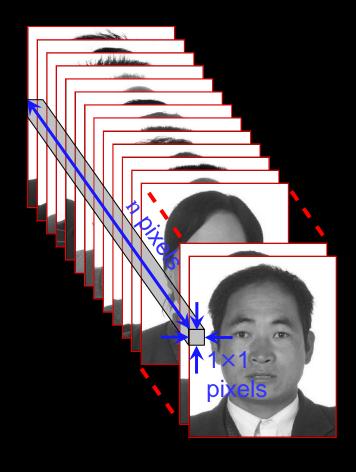

Image Compression

Facial Image Compression

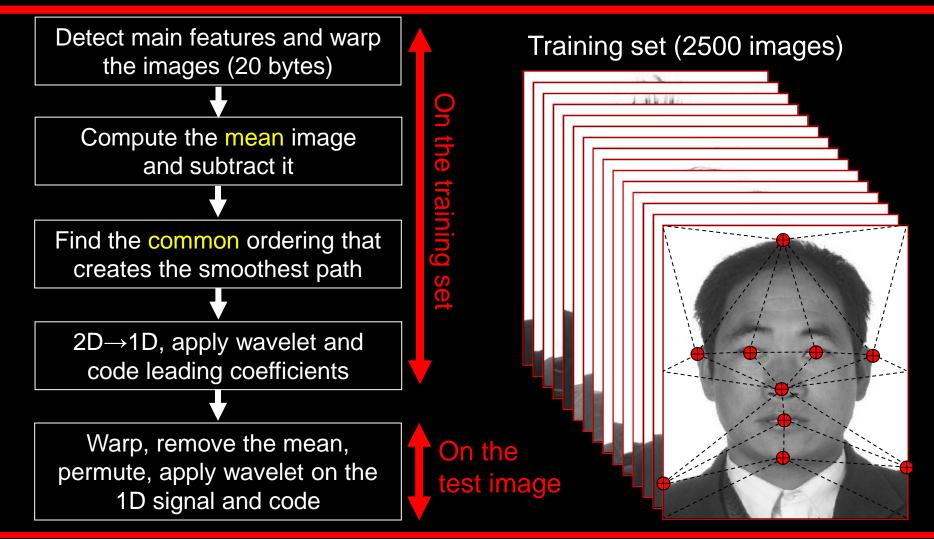

□ The problem: Compressing photo-ID images.

- General purpose methods (JPEG, JPEG2000) do not take into account the specific family.
- By adapting to the image-content (e.g. pixel ordering), better results could be obtained.
- For our technique to operate well, we find the best common pixel-ordering fitting a training set of facial images.
- Our pixel ordering is therefore designed on patches of size 1×1×n pixels from the training volume.
- Geometric alignment of the image is very helpful and should be done [Goldenberg, Kimmel, & E. ('05)].

Rate-Distortion Curves

Part V

Time to Finish

Conclusions

2D to 1D conversion is not necessarily a bad idea, and especially so if done in an image adaptive way We propose such a 1D ordering based on approximating the shortest path in the patch domain We demonstrate the effectiveness of this approach to image denoising, inpainting and compression

What next? Many things ...

Use this paradigm for general inverse problems
 Why just permutation and not other orderings
 Merge with statistical modeling of images
 Improve the TSP approximation

Thank you to Chen Sagiv and Jacob Cohen for a very interesting event and for inviting me
